BISIGLES

Motivation: Potential future Sea Level Rise

- ❑ Potentially large Antarctic contributions to SLR resulting from marine ice sheet instability, particularly from WAIS.
- ❑ Climate driver: subshelf melting driven by warm(ing) ocean water intruding into subshelf cavities.
- ❑ Evidence that this is already underway in ASE sector. (elsewhere, too?)
- ❑ Paleorecord implies that WAIS has deglaciated in the past.

Antarctic vulnerability to warm-water forcing

- ❑ Basic idea - try to understand where AIS is vulnerable to forcing from warm-water incursions

Antarctic sectors

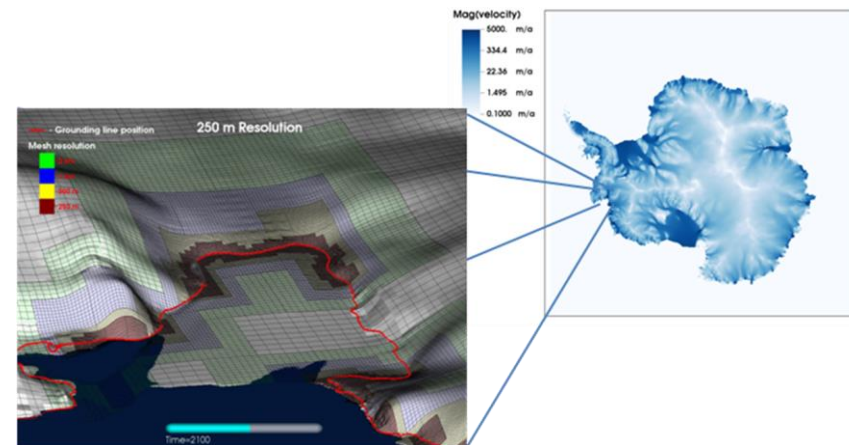

- ❑ Divide AIS into sectors
- ❑ For each sector in turn (and for some combinations), apply extreme depth-dependent melt forcing
 - No melt for $h < 100\text{m}$
 - Range up to 400m/a where $h > 800\text{m}$.
 - No melt applied in partially-grounded cells

- ❑ Run for 1000 years, compare with control (no melt).

BISICLES Ice Sheet Model

- ❑ Scalable adaptive mesh refinement (AMR) ice sheet model
 - Dynamic local refinement of mesh to improve accuracy
- ❑ Chombo AMR framework for block-structured AMR
 - Support for AMR discretizations
 - Scalable solvers
 - Developed at LBNL
 - DOE ASCR supported (FASTMath)
- ❑ Collaboration with Bristol (U.K.) and LANL
- ❑ Variant of “L1L2” model (Schoof and Hindmarsh, 2009)
- ❑ Users in Berkeley, Bristol, Beijing, Brussels, and Berlin...
- ❑ **Release v 1.0!**

Initial Condition for Antarctic Simulations

- ❑ Full-continent modified Bedmap2 (2013) geometry
- ❑ Temperature field from Pattyn (2010)
- ❑ Initialize basal friction to match Rignot (2011) velocities
- ❑ SMB: Arthern et al (2006)
- ❑ AMR meshes: 8 km base mesh, adaptively refine to $\Delta x_f = 1$ km
- ❑ Subgrid-scale basal friction scheme at grounding lines
 - (Cornford et al, 2016 - adequate for Antarctic GL dynamics)

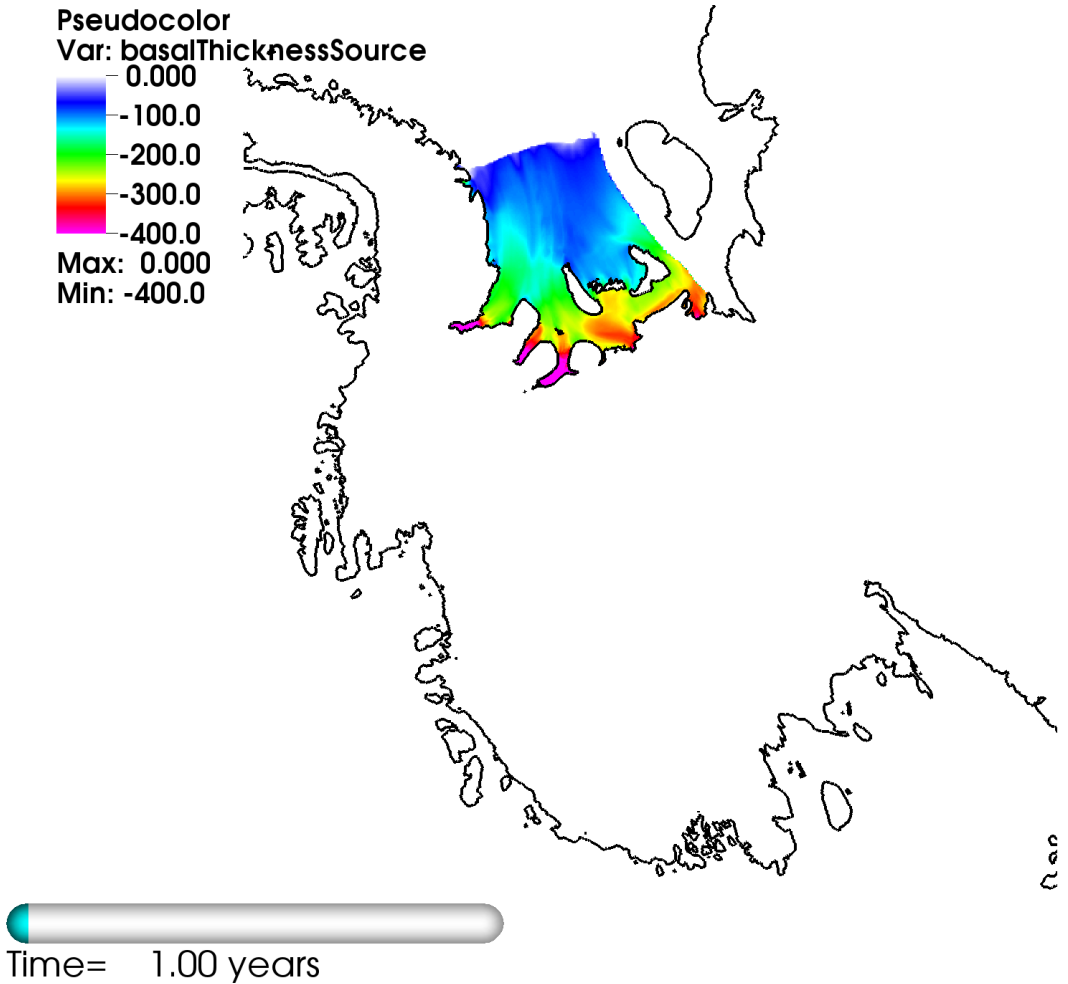

Results -

Change in VoF (mm SLE)

Change in Volume over flotation relative to control

Sector 5, cont

ENERGY

Office of
Science

BISICLES

Sector 5, cont

Sector 5 (Western Ronne)

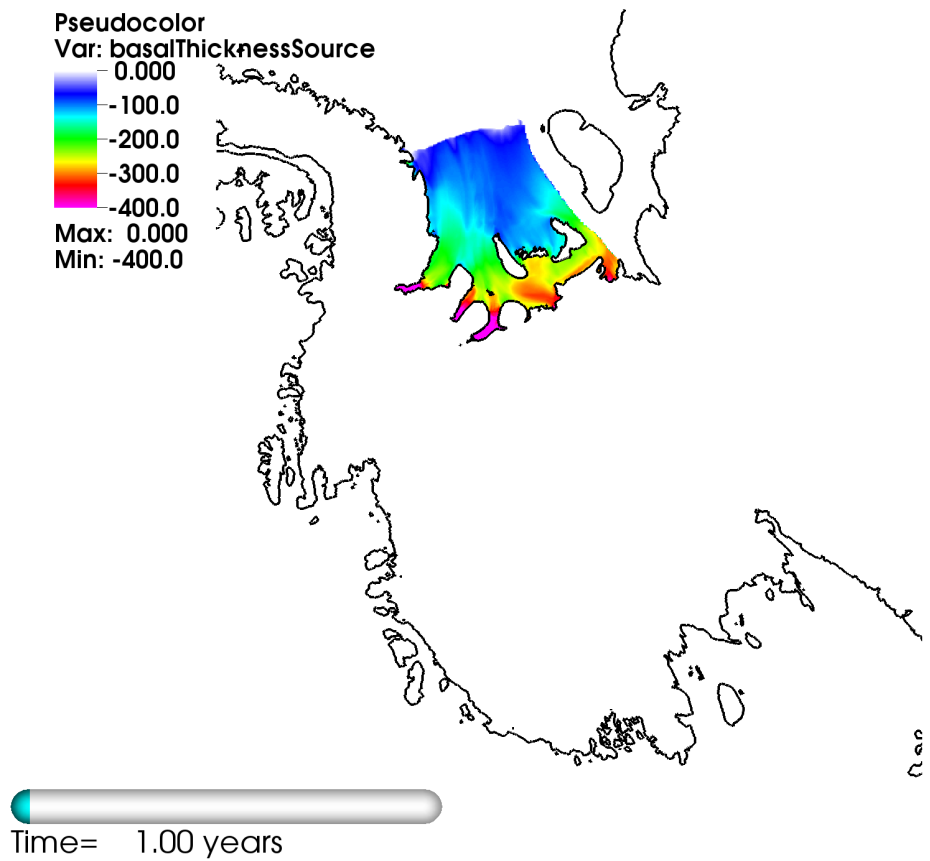

- ❑ GL retreat moves out of sector...
- ❑ Substantial retreat into WAIS even after direct forcing ends
- ❑ 1.03 m SLE

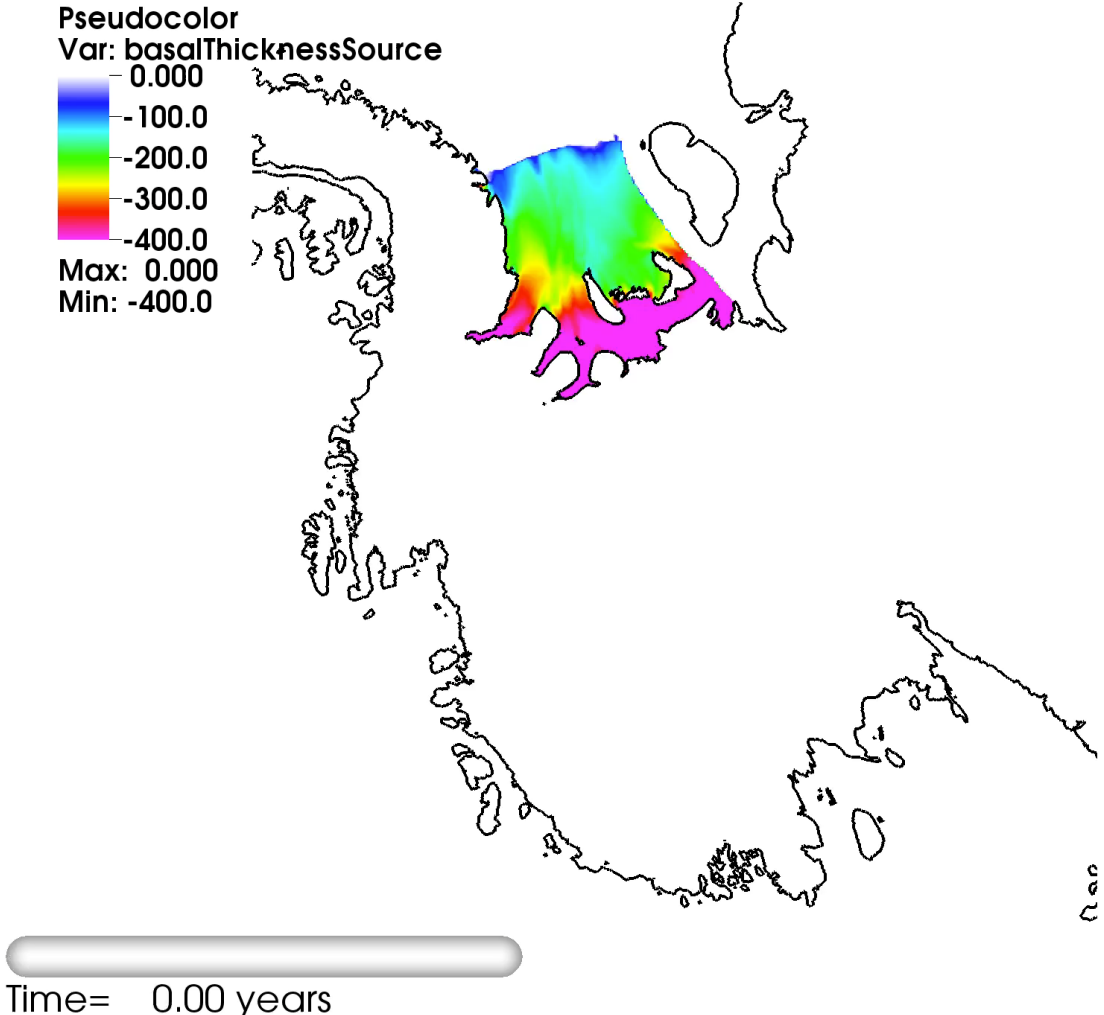

Change in Ice Thickness

Sector 5 - interior melting

Sector 5, interior melting

U.S. DEPARTMENT OF ENERGY

Office of Science

BISICLES

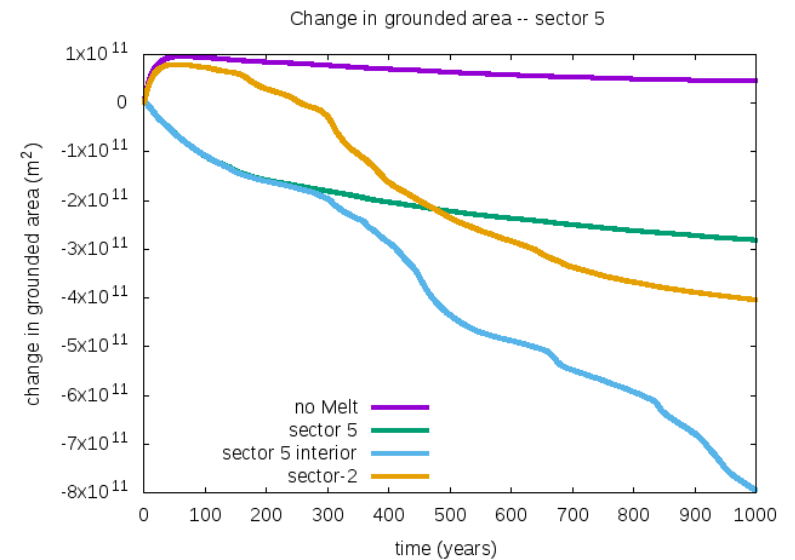

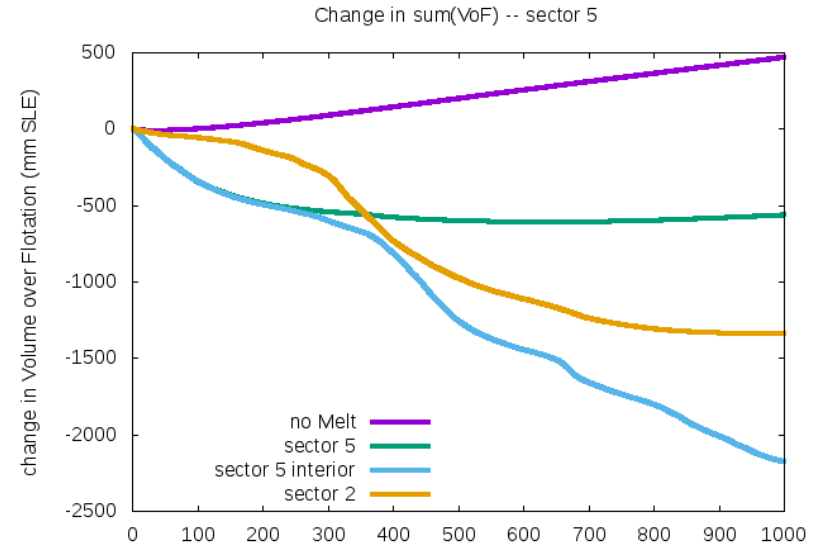

Sector 5 -- Interior melting..

- Allow melt to follow GL into interior

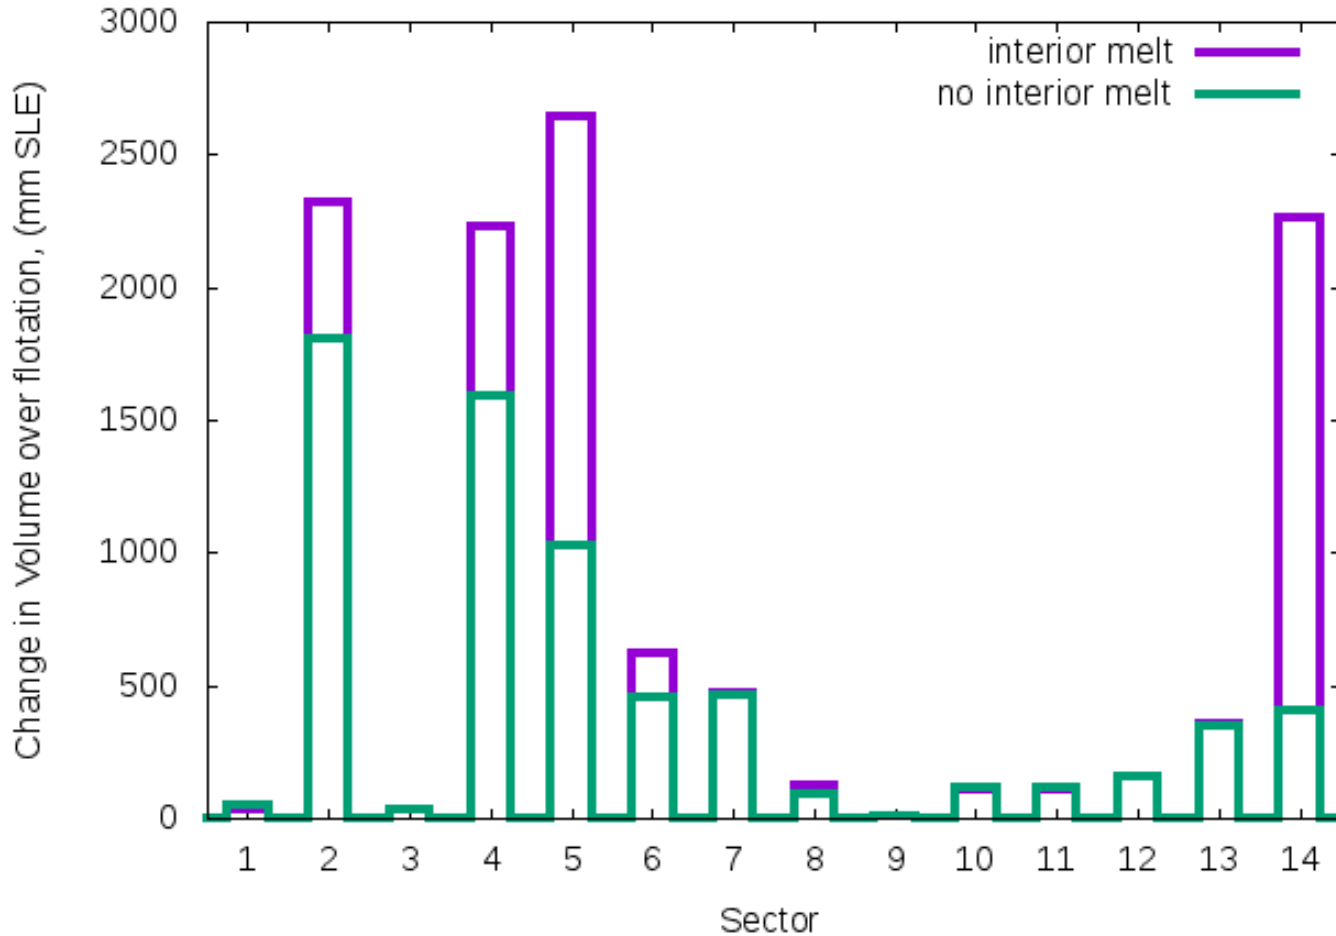

- Increase to 2.64 m SLE (from 1.03 m SLE)

Results - contribution to SLR

Final contribution to SLR by sector

Sector 2 (ASE)

Change in Ice Thickness

Sector 2 (ASE): 1.8m SLE

Sector 2-interior: 2.3m SLE

Sector 13

Change in Ice Thickness

Sector 13: 0.345 m SLE

What about Totten?

- ❑ With Bedmap2 topography, limited vulnerability..
- ❑ Sector 12 - 0.156m SLE

Change in Ice Thickness

Combinations: 2 (ASE) & 4 (Ross), 2&5 (Ronne)

Change in Volume over Flotation, sectors 2+4

Change in volume over flotation, sectors 2+5

- Green, purple - single sectors
- Blue - combination of the two
- Yellow - sum of the two single-sector runs
- For WAIS sectors, roughly independent at start, after O(200a), start to interact

What about Cliff Collapse?

Background:

- ❑ Deconto and Pollard (2015) - wanted to be able to match paleorecord of large SLR
- ❑ Surmised mechanism:
 - hydrofracture (eliminate ice shelves)
 - Cliff collapse (drive retreat into EAS basins)
 - Allows for much greater SLR

What about Cliff Collapse? (cont)

U.S. DEPARTMENT OF
ENERGY

Office of
Science

BISICLES

Mag(surface Gradient)

Our results...

- ❑ Can look at local slopes to see if we get “cliffs”
 - Yes, but sporadic and ephemeral

- ❑ Best guess is 2 factors in play
 - BISICLES is able to resolve the ice front/margin
 - Spatially & temporally
 - See large drawdowns of ice thickness in interior

- ❑ Provisional conclusion - cliff-collapse not the answer here?

- ❑ (next step - implement a cliff-collapse model in BISICLES and test)

Conclusions (and caveats)

- ❑ Primary vulnerability still WAIS.
- ❑ Limited potential from EAS
- ❑ WAIS vulnerable from any of three sectors
 - (2 of which are large cold ice shelves)

- ❑ Intermediate vulnerability in Filchner, Western Ross

- ❑ Assumption of basin independence OK for a few hundred years
- ❑ Cliff collapse doesn't appear to be a factor - no cliffs!
 - Diffusive thinning upstream
 - High spatial and temporal resolution

- ❑ Everything dependent on Bedmap2 geometries...

Thank you!

Extras

Results -- summary

Change in grounded area vs time

Change in Sum (Volume over Flotation)

- WAIS-connected sectors (2,4,5) - largest response
- Intermediate response from 6,7,13,14
- Sector 11 - issues with Bedmap2

WAIS - 1km Resolution with GLI

Mesh evolution (500m mesh)

Mesh evolution (500m finest mesh)

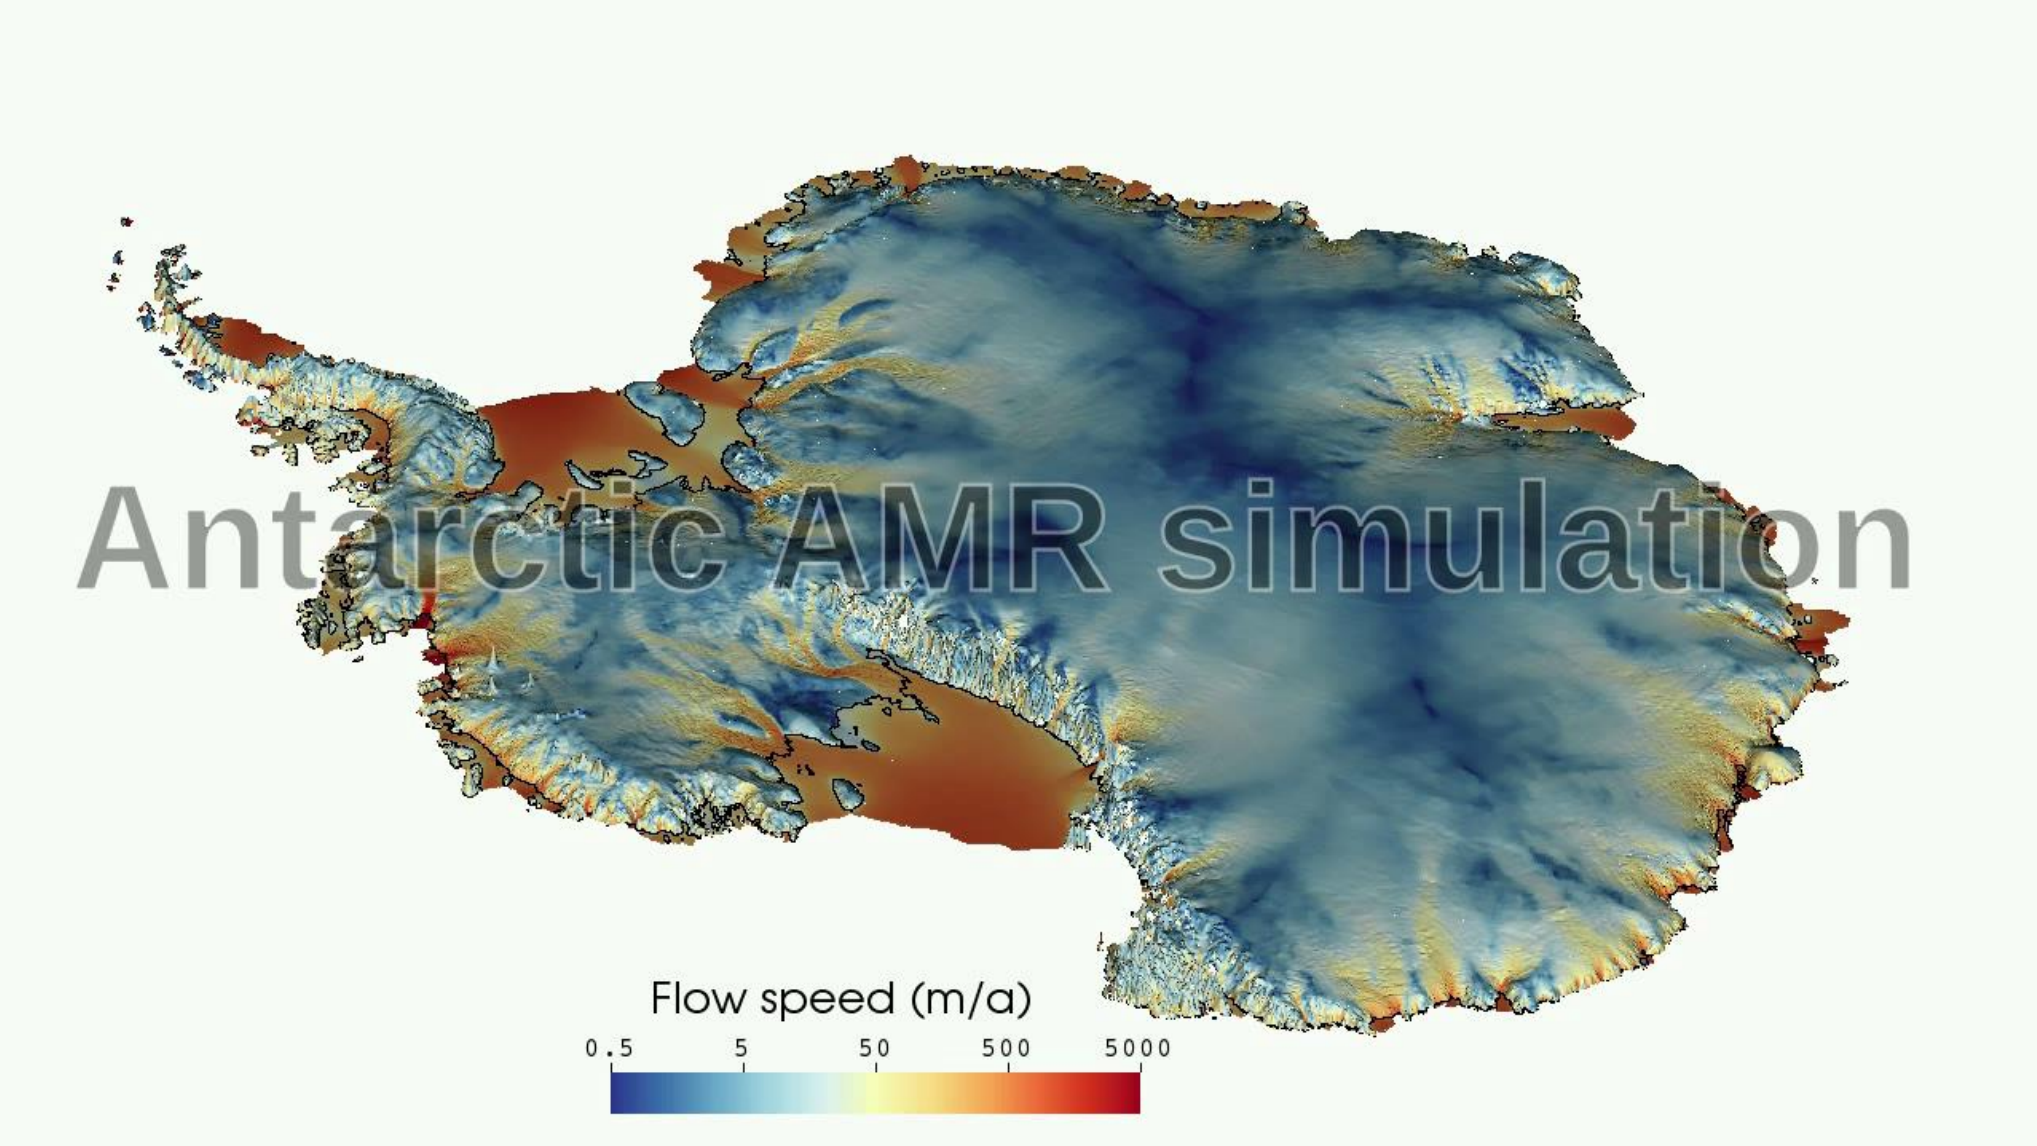

Experiment - 1000-year Antarctic simulations

- ❑ Range of finest resolution from 8 km (no refinement) to 500m (4 levels of factor-2 refinement)
- ❑ Subgrid basal friction parameterization (e.g. Seroussi et al)
 - Experience shows that it buys us about a factor of 2x
- ❑ At initial time, subject ice shelves to extreme (outlandish) depth-dependent melting:
 - No melt for $h < 100\text{m}$
 - Range up to 800m/a where $h > 400\text{m}$.
 - **No melt applied in partially-grounded cells**
- ❑ For each resolution, evolve for 1000 years

Results:

U.S. DEPARTMENT OF
ENERGY

Office of
Science

BISICLES

Results, cont.

- Upper plot - Change in VoF
 - Convergent at sufficient resolution
- Lower plot -- Rate of Change
 - Big spike - WAIS collapse
 - Timing is a function of resolution

Questions we'd like to answer:

- ❑ **Assess vulnerabilities:**
 - Where is the Antarctic Ice Sheet vulnerable to instability driven by warm-water incursion into subshelf cavities?

- ❑ **Assumption of basin independence**

Intermediate loss sectors

Thwaites-Rutford - effect of resolution
